

Module 1 - Identifying uses cases and predictors – Summary and key points

- 01** Detecting use cases starts with an **in-depth analysis of the company's processes** and their components.
- 02** **AI can bring great value when repetitive tasks, complex manual steps, or hot spots for error, delay, or improvement opportunities are identified.**
- 03** Company business processes, whether in production, accounting, supply chain management, or other areas, need to be reviewed and broken down.
- 04** **Tasks and processes requiring significant human intervention, such as auditing or paper document management, need to be identified for consideration of automation through AI,** particularly with Deep Learning.
- 05** **Repetitive tasks, which are performed in a similar way from one instance to the next, are good candidates for automation by AI** for consistent, human-error-free execution.
- 06** Points of slowdown or inefficiency in processes need to be located, and their causes, whether technical, legal or linked to limited resources, analyzed. AI can speed up these operations.
- 07** It is essential to understand how data flows within the company, identifying the key points where decisions are made. **AI can analyze complex data to provide insights and recommendations.**
- 08** AI can be used in many different ways. Examples include AI "**at the service of machines**" (predictive maintenance of production equipment, autonomous cars, etc.), AI "**at the service of employees/users**" (customer service chatbots, information retrieval, etc.) and AI "**at the service of software engineering**" (development assistance, code review).
- 09** A group of employees who work with processes and data on a daily basis can provide crucial insights to identify weak points and opportunities for improvement through AI. Consulting specialist AI providers, especially those with expertise in a specific business area, can help identify relevant use cases.
- 10** If the company already has AI use cases in place, it is important to ensure that they are well optimized and meet expectations, with regular evaluation of their performance and the opportunity to challenge existing algorithms.
